

Remote Control

Objective: To perform reconnaissance activity through a compromised machine to prevent detection

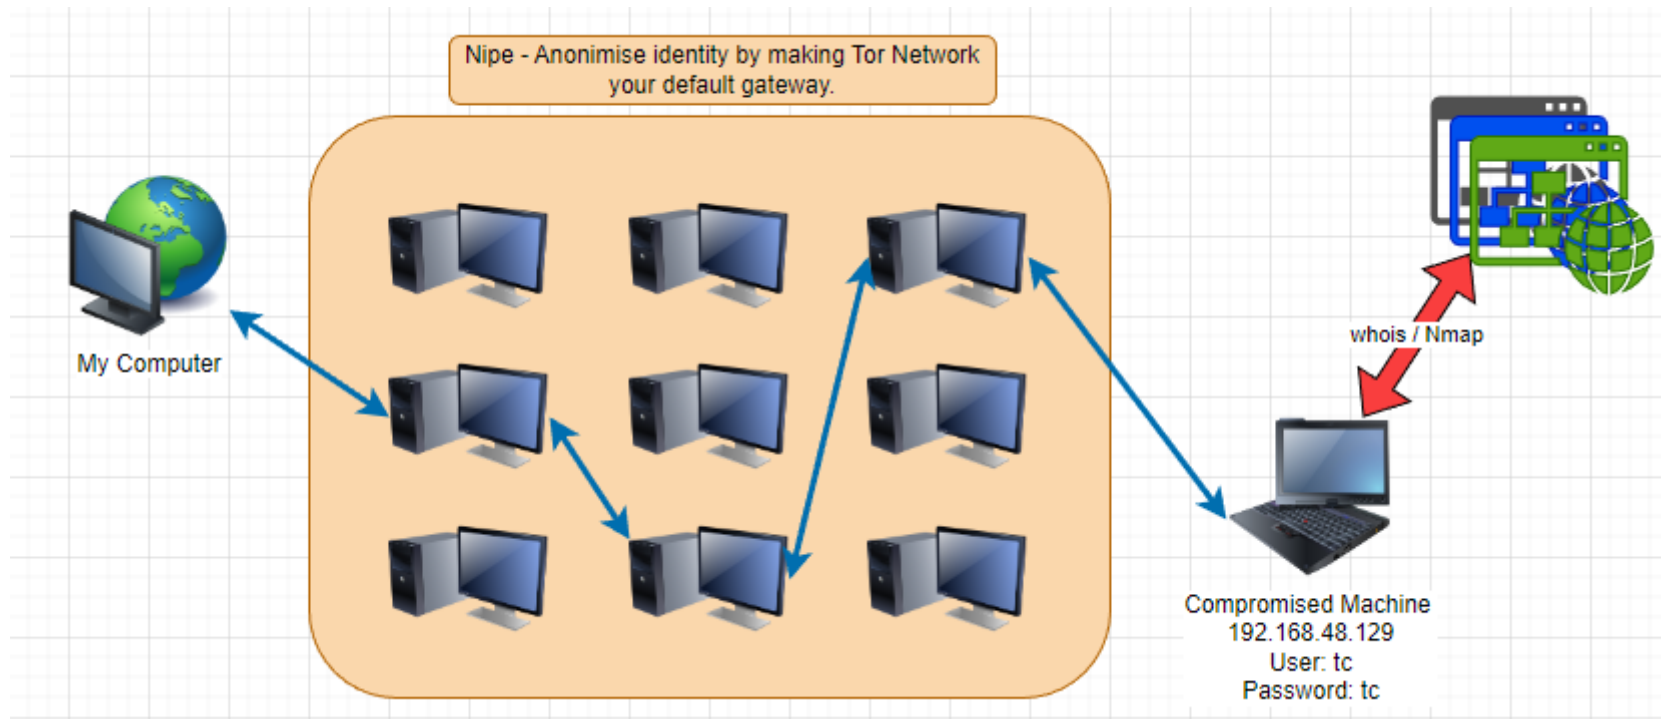

Figure A -Script operation overview

In Figure B, User can choose to use 'source ~/Documents/script/remotectlrv1.sh' to run the script from any current working directory point to the path where the shell script is being stored. Alternatively, the user can also choose to go to the working directory of the shell script to execute 'bash remotectlrv1.sh'

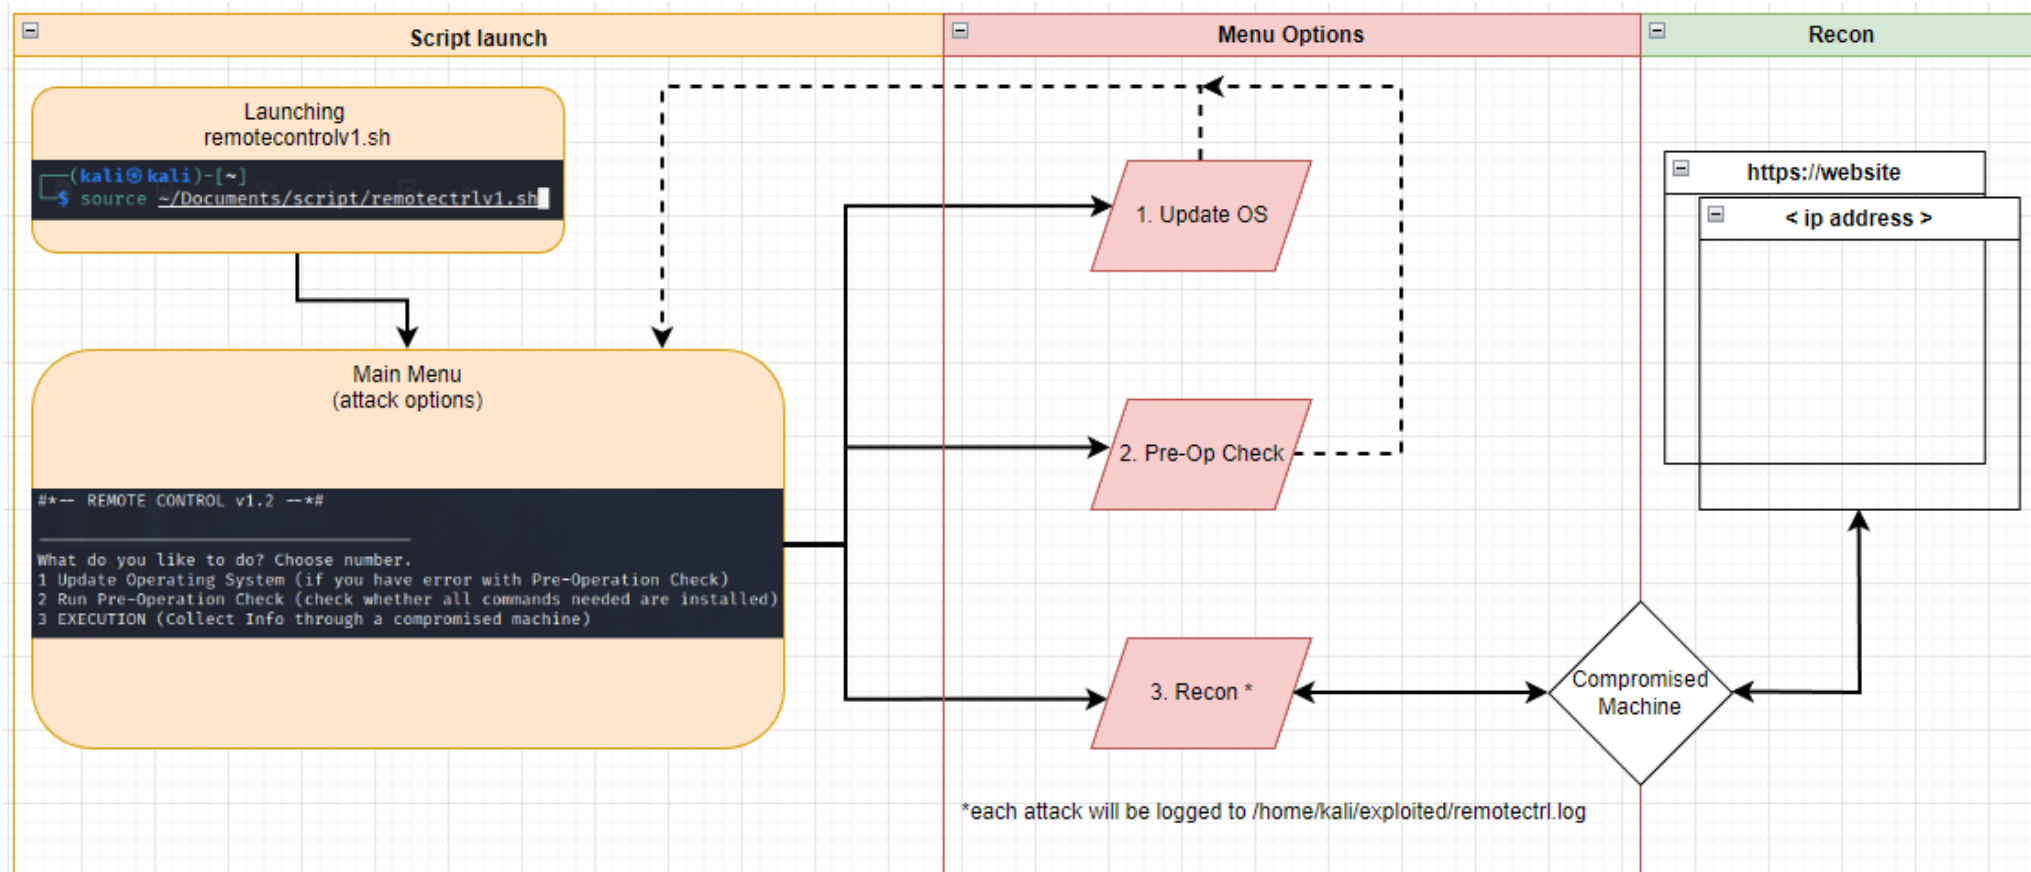

Figure B -Process flow of Script

Updating Operating System

In Figure 1, User can choose the option to update and upgrade the Operating System (OS). User can choose this if one finds error when running Pre-Operation check, which is usually caused by outdated OS. When using 'sudo' command, it is usually an interactive shell command. Since we are using a script, we will want it to be as non-interactive as possible. We can turn it into non-interactive by using '-S' flag. In line 23, we feed the password, in our case is 'kali', by piping echo <password> before 'sudo' command. By using '2>/dev/null', we can discard the password prompt message to achieve a clean terminal output.

Once the system has pulled the necessary packages, it will prompt user to input 'y' to upgrade (line 30) or 'n' to not upgrade and return to main menu (line 38). If it receives any other input, it will notify user and prompt user again (line 42).

```
19 #This Option allows user to check for update and upgrade of Operating System
20 #sudo -S receives password input by echo-ing password'kali' before sudo command
21 1)
22 echo "Checking and updating Linux System.."

Figure 2 Terminal Output of Option 1: Update Operating System

Pre-Operation Check

Pre-Operation Check is offered as Option 2 in the Main Menu. This makes sure that the host machine has the required tools to be able to perform the actual task which is offered as Option 3.

In Figure 3, line 64, 'command -v' is used to check if 'sshpass' command is installed in the machine, if not it will execute line 70 to install the package. Here, we used '>/dev/null/' to discard any message that will be shown on terminal. In Figure 4, the same script is used with slight alteration in line 80 and line 86 to check for 'whois' command.

```
61 # sshpass is a non-interactive ssh password authentication tool to remote access the compromised machine to do recon activities
62 function installsshpass()
63 {
64     if command -v sshpass >/dev/null
65     then
66         echo '[+] sshpass is installed'
67         return
68     else
69         echo '[-] sshpass NOT installed, installing...'
70         echo kali | sudo -S apt-get install sshpass -y 2>/dev/null
71     fi
72     installsshpass
73 }
74
75 installsshpass
```

Figure 3 Function to check and install sshpass to provide non-interactive ssh login

```
77 # Whois is used find out information about a website's record, like ip address, site's owner and site's origin etc
78 function installwhois()
79 {
80     if command -v whois >/dev/null
81     then
82         echo '[+] whois is installed'
83         return
84     else
85         echo '[-] whois NOT installed, installing...'
86         echo kali | sudo -S apt-get install whois -y 2>/dev/null
87     fi
88     installwhois
89 }
90
91 installwhois
```

Figure 4 Function to check and install whois

In Figure 5, the command used to check for nipe differs from the 'sshpas' and 'whois' as it is not an official package in linux and was created by Heitor Gouvêa and published in github. Nipe will be installed in the current working directory in the terminal where User execute the command. In Figure 5 line 96 and line 103, nipe was chosen to be installed in /home/kali for ease of access to the nipe working directory. Line 104 to 106 is the terminal commands used to install nipe.

```
92      # Nipe is an engine that makes the Tor network our default network gateway.
93      function installnipe()
94      {
95          # 'test -d' tests if this application exist in the directory as it is not installed in /usr/bin like other common applications
96          if test -d /home/kali/nipe
97          then
98              echo '[+] Nipe is installed'
99              cd /home/kali/nipe
100             return
101          else
102              echo '[-] Nipe not found. Installing nipe..'
103              cd ~
104              git clone https://github.com/htrgouvea/nipe && cd nipe
105              echo kali | sudo -S cpan install Try::Tiny Config::Simple JSON 2>/dev/null
106              echo kali | sudo -S perl nipe.pl install 2>/dev/null
107              cd /home/kali/nipe
108              return
109          fi
110          installnipe
111      }
112      installnipe
```

Figure 5 Function to check and install nipe engine

In Figure 6, line 117 checks if the directory to stores the log and information is present, if not it will proceed to create the required directory and sub-folders to prevent any storage errors when executing 'sshpas' later on to store the information that the User have executed.

```
114      # LOGDIR checks if the directory that will store our log and collected info exists, if not it will create it.
115      function LOGDIR()
116      {
117          if test -d ~/exploited && test -d ~/exploited/whois && test -d ~/exploited/nmap
118          then
119              echo "[+] Directory '~/exploited' ready for storing log"
120              return
121          else
122              echo -e "\n>> no log directory. creating in process.. <<"
123              mkdir ~/exploited && mkdir ~/exploited/whois && mkdir ~/exploited/nmap
124          fi
125          LOGDIR
126      }
127      LOGDIR
128
129      REMOTE
130      }
131      PRECHECK
132      ;;
```

Figure 6 Function to check and create directory for log and storing information

Figure 7 shows the terminal output of after running Option 2 (Run Pre-Operation Check). Once all the necessary checks have been done, it will display status as [+] and User can proceed to use Option 3 (EXECUTION) to perform the main task. If there is error when installing the package as shown in Figure 8, User should consider running Option 1 to update and upgrade the Operating System and then running Option 2 again.

```

Figure 8 Error Output when installing sshpass

Execution

Figure 9 shows the first part of Execution. Anonymity check is placed into this part instead of Option 2(Pre-Execution Check) as a safety measure. After repeated usage of the script from the same user, one may forget to run Option 2 due to convenience, thus placing the User at risk of identity exposure. At times, the nipe engine may fail to start and return no ip address at all, especially when the user just started up his machine. Line 155 to 158 aims to resolve this until the engine can output an IP address. However, it doesn't guarantee that a foreign ip address have been successfully used as our default gateway, so Line 160 and 167 will compare with our original public IP. When *spoofip* is not the same as *myip*, the script will determine that User can safely carry out his next activity, if not it will not allow user to carry out the next activity.

```
139 # ANONCHECK checks if User have successfully spoofed a foreign IP address using Nipe application
140 # This is to ensure identity anonymity to prevent traceback before executing activities
141 function ANONCHECK()
142 {
143     clear -x
144     echo "Checking Anonymity..."
145     # Declaring variables.
146     # myip is User's machine IP, which can be changed when this script is used by another machine
147     # niperr is used to start Nipe
148     # spoofip and spoofcc stores the spoofed ip and country code
149     myip='101.127.159.84'
150     niperr=$(echo 'kali' | sudo -S perl nipe.pl restart 2>/dev/null)
151     spoofip=$(curl -s ifconfig.io)
152     spoofcc=$(curl -s ifconfig.io/country_code)
153     echo -e "\n[*] Your Public IP is $myip"
154     # if spoofip returns an empty string, it will call function ANONCHECK to start nipe again
155     if [[ -z "$spoofip" ]]
156     then
157         echo "spoof is warming up.."
158         ANONCHECK
159     # once spoofip is not empty, it will compare with User's IP to ensure anonymity
160     elif [[ "$myip" != "$spoofip" ]]
161     then
162         echo "[+] You are ANONYMOUS now!"

164         echo "[*] Your spoofed Country: $spoofcc"
165         sleep 2
166         return
167     elif [[ "$myip" == "$spoofip" ]]
168     then
169         echo "[X] ALERT ALERT! You are traceable! Exiting.."
170         cd /home/kali/nipe
171         sudo perl nipe.pl stop
172         sleep 2
173         exit
174     fi
175     ANONCHECK
176 }
177 ANONCHECK
```

Figure 9 Option 3- Execution (Part 1): Anonymity Check

Figure 10 shows the Second part of Execution. From Line 191 to 193, the script checks if the User has input a valid IP Address, if it is not, then it will prompt user to input a valid IP again. If the User gives a domain address, it will carry out the script in Figure 11, which is largely similar with minor alteration to the head and tail of the script to suit the usage for domain address input.

From line 197, the argument is passed to check if the User machine is able to connect to the compromised machine. If not, in line 218, it will notify User that the machine is not available and carry out Execution with another compromised machine. Once User have successfully accessed the compromised machine in, the script checks the computer details like Uptime, IP address and Location. It will then proceed to collect information using 'nmap' and 'whois' into User's local machine.

```

184 # EXPLOIT checks if you have entered a valid ip address or domain name and proceed to execute NMAP & WHOIS and log activity in my local computer
185 # My ubuntu(192.168.48.129) is used as the compromised Remote Server
186 function EXPLOIT()
